

Exercises HMM Inference

Hidden Weather and Umbrellas

We model the daily weather as a Hidden Markov Model with *hidden state*

$$X_t \in \{\text{Rainy (R)}, \text{Sunny (S)}\}$$

and *observations*

$$E_t \in \{\text{Umbrella (U)}, \text{No Umbrella (N)}\},$$

indicating whether your colleague carries an umbrella on day t .

Model parameters

Initial distribution.

$$P(X_1 = R) = 0.5, \quad P(X_1 = S) = 0.5.$$

Transition model.

$$\begin{aligned} P(R | R) &= 0.7, & P(S | R) &= 0.3, \\ P(S | S) &= 0.8, & P(R | S) &= 0.2. \end{aligned}$$

Observation model.

$$\begin{aligned} P(U | R) &= 0.9, & P(N | R) &= 0.1, \\ P(U | S) &= 0.2, & P(N | S) &= 0.8. \end{aligned}$$

Observation sequence

Over four consecutive days you record:

$$e_{1:4} = (U, U, N, U).$$

Tasks

(A1) Forward algorithm (filtering).

Use the forward algorithm to compute the joint quantities

$$\alpha_t(x) = P(e_{1:t}, X_t = x)$$

for $t = 1, 2, 3, 4$ and for $x \in \{R, S\}$. Then compute the *filtered beliefs*

$$P(X_t = x | e_{1:t}) = \frac{\alpha_t(x)}{\sum_{x'} \alpha_t(x')}$$

for each t and x .

Present your results in a table with columns t , $\alpha_t(R)$, $\alpha_t(S)$, $P(X_t = R | e_{1:t})$, $P(X_t = S | e_{1:t})$.

(A2) Viterbi algorithm (most likely state sequence).

Use the Viterbi algorithm to compute the most likely sequence of hidden weather states given the observations:

$$x_{1:4}^* = \arg \max_{x_{1:4}} P(x_{1:4} \mid e_{1:4}).$$

Show the dynamic programming recurrence for the Viterbi scores $\delta_t(x)$ and backpointers, and give the final most likely sequence $x_{1:4}^*$.
